1.0 INTRODUCTION

1.1 Objective

The objective of this project is to design two culvert replacements for two fish passage sites in the Copper River Delta near Cordova, Alaska. The replacement culverts will improve fish passage and ecologic function at the road crossings of Sheridan River Tributary by simulating the natural creek channel and provide conveyance of at least the 100-year flood flow. The culverts will also enhance maintenance conditions at each crossing and reduce the likelihood of future infrastructure damage caused by flooding along the road. The Sheridan River Tributary is an anadromous stream that flows south to Sheridan River. The Copper River Watershed and Delta is a system of relic channels, connected upstream and downstream, with base flows that are continuously changing over time. The project crossing drainage basin is shown in Figure 1.

The Sheridan River Tributary stream crossings have been identified as No. 20100475 (COP 9) and No. 20101903 (SHER 1) in the FPID. COP 9 has been given a Green rating and SHER 1 has been given a Red rating. These crossings have been identified by ADF&G, United States Fish and Wildlife Service (USFWS), Copper River Watershed Project (CRWP), United States Forest Service (USFS), and the National Oceanic and Atmospheric Administration (NOAA) as an impediment and barrier to upstream fish migration as well as causing disruption to the Delta's hydrology, reducing its ecological function.

To meet project objectives, a topographic survey of the project area was completed to facilitate hydraulic modeling. A geomorphic analysis was used to assess sediment transport and incorporate natural channel characteristics into the design. A geotechnical analysis, completed in April 2019 by others, was used to investigate subsurface soil conditions at the four crossings. Design alternatives were evaluated to determine the most economical means of replacing the existing structures to improve ecological function and flood conveyance.

1.2 Existing Conditions

SHER 1 is located on Goat Camp Road, upstream of COP 9. The existing culvert at SHER 1 is 1.5 feet in diameter and 54 feet long. The culvert has a gradient of 2% and a constriction ratio of 0.11. The existing culvert is backwatered and fully submerged. SHER 1 was given an overall fish passage rating of Red in 2011 by ADF&G. There is an old, damaged 8-foot pipe located north of the SHER 1 crossing on Goat Camp Road that is not in use.

COP 9 is located on the Copper River Highway, downstream of SHER 1. The existing culvert at COP 9 is 4 feet in diameter and 65 feet long. The culvert has a gradient of 1% and a constriction ratio 0.35. Corrosion has been observed on the existing culvert with a rust line of 1.9 feet. There is riprap placed within the culvert. The culvert was given an overall fish passage rating of Green in 2011 by ADF&G.

Figure 1: COP 9 and SHER 1 Drainage Basin

1.3 Design Criteria

The geomorphic analog method is the preferred design approaches for the SHER 1 and COP 9 crossings of the Sheridan River Tributary. The design of the proposed fish passage culverts is based on criteria and guidelines contained in the USFWS *Fish Passage Design Guidelines* (*Revision 6*) released June 2021, which follows the United States Forest Service (USFS) stream simulation approach with modifications. The USFS stream simulation approach is described in the 2008 Stream Simulation: An Ecological Approach to Providing Passage for Aquatic Organisms at Road-Stream Crossings. Key criteria from the sources include:

- The constructed channel within the crossing shall not differ from the reference reach condition under normal flow conditions regarding channel width, cross-sectional area, gradient, substrate, and ability to pass floating debris;
- The culvert width shall be at least 1.0 times bankfull width, with a minimum diameter of 5 feet;
- The embedment depth shall be the greater of 40 percent of the diameter or two feet for circular culverts;
- Embedment depth shall be the greater of 20 percent of the rise or two feet for all other culverts;
- Substrate material within the crossing shall be dynamically stable up to and including the 50-year flood;
- Stream banks inside the culvert shall be stable up to and including the 100-year flood;
- A continuous low flow channel that simulates the reference reach shall be incorporated in the substrate material;
- Culvert gradient shall be within 25% of the natural channel grade;
- Culverts shall be corrugated.
- Structures shall be designed to accommodate at least the 100-year flood flow, preferably with a headwater-to-depth (HW/D) ratio of 0.8.

1.4 Right-of-Way and Utilities

The Copper River Highway is owned by Alaska Department of Transportation and Public Facilities. The Copper River Highway is centered within a 200-foot-wide right-of-way (ROW).

A fiber optic vault is located south of the Copper River Highway near the intersection with Goat Camp Road and south of the SHER 1 crossing. A fiber optic line runs along the south side of the Copper River Highway under COP 9 and SHER 1 crossings. The line is at approximately 41.5' El at COP 9 and 56.0' at SHER 1. The fiber optic lines enter the utility vault at a 45-degree angle. Cordova Telephone Cooperative has been contacted regarding the crossings and potential reburial of the line for the SHER 1 crossing.

2.0 GEOTECHNICAL CONDITIONS

A geotechnical investigation consisting of two borings at each crossing was conducted at the two fish passage crossing locations by Northern Geotechnical Engineering, Inc. in April 2019. The geotechnical report for USFWS Fish Passage Improvements was completed by Northern

Geotechnical Engineering, Inc. The subsurface conditions, soil bearing capacity, and sitespecific geotechnical construction recommendations are summarized below.

2.1 SHER 1

2.1.1 <u>North</u>

- 0 to 7 feet: Well graded sand with silt and gravel. Groundwater encountered at approximately 6.5 feet.
- 7 to 9.5 feet: Silty sand.
- 9.5 to 13 feet: Poorly graded sand with gravel.
- 13 to 15: Silty sand.
- 15 to 21.5 feet: Poorly graded sand.

2.1.2 Soil Bearing Capacity

The allowable soil bearing capacity of 3,900 pounds per square foot may be used for a box culvert foundation on undisturbed sand and gravel or compacted structural fill.

2.1.3 Construction Recommendations

Site bearing soils approximately 11 to 12 feet below the road surface consist of loose poorly graded sand with silt and gravel. Excavation is required a minimum of 2 feet below the bottom of the culvert. Then placement of geotextile, reinforcement, type 2 and Subbase, Grading F material is required, as described Section 2.4.

2.2 COP 9

2.2.1 Upstream

- 0 to 4.5 feet: Poorly graded gravel with sand.
- 4.5 to 9.5 feet: Poorly graded sand with silt and gravel. Groundwater encountered at approximately 7 feet.
- 9.5 to 12 feet: Well graded gravel with silt and sand.
- 12 to 14.5 feet: Poorly graded sand with gravel.
- 14.5 feet to 21.5: Sandy silt.

2.2.2 <u>Downstream</u>

- 0 to 12 feet: Well graded gravel with silt and sand. Groundwater encountered at approximately 9 feet.
- 12 feet to 21.5: Silty sand.

2.2.3 Soil Bearing Capacity

The allowable soil bearing capacity of 3,900 pounds per square foot may be used for a box culvert foundation on undisturbed sand and gravel or compacted structural fill.

2.2.4 <u>Construction Recommendations</u>

Site bearing soils approximately 13 to 15 feet below the road surface consist of loose to medium dense silty sand to sandy silt. Excavation is required a minimum of 2 feet below the bottom of the culvert. Then placement of geotextile, reinforcement, type 2 and Subbase, Grading F material is required, as described Section 2.4.

2.3 Summary

Additional recommendations provided in the geotechnical report include using culvert embedment material Subbase, Grading F, extended one foot below the bottom of the culvert, 18 inches to both sides of the culvert, and a minimum of one foot above the culvert. A layer of geotextile, reinforcement, type 2 should be placed between the Subbase, Grading F material and the native soil or Type A material. A layer of geotextile, reinforcement, type 2 should be placed between each one-foot layer of Subbase, Grading F material.

3.0 GEOMORPHIC ANALYSIS

A site investigation was conducted on July 20 through 23, 2021. During the site visit, DOWL engineers took channel measurements, conducted pebble counts, and observed bedform features. The reconnaissance-level map, field notes, and pebble count data from the site investigation are included in Appendix A. DOWL engineers and United States Fish and Wildlife revisited the site on August 2nd and 3rd to take discharge measurements and bankfull width dimensions.

3.1 Stream Morphology and Crossing Characteristics

3.1.1 <u>SHER 1</u>

The Sheridan River tributary flowing to the SHER 1 crossing originates in the marsh-wetlands southeast of the Sheridan River.

Upstream of the Goat Camp Road crossing, the Sheridan River tributary is a meandering stream. The predominant bedform features consist of slow, long pools with riffle sections, and areas of split flow and ponded water. Upstream is low gradient and heavily wooded with grassland. The stream substrate consists of fine to very course gravel with areas of organics. Riparian vegetation includes grasses, moss, fern, alder, and willow. The floodplain is wide and unconfined. A beaver pond (old gravel pit) is located approximately 525 feet upstream of the SHER 1 crossing.

Downstream of the SHER 1 Goat Camp Road crossing, the Sheridan River tributary currently follows the Copper River Highway and flows into COP 9. The stream flows through a marsh area and the predominant bedform features consist of riffles and pools. Bank instability is indicated by several vegetated bars within the channel. The stream substrate consists of very fine to very coarse gravel with sections of sand and organics. It is a stable, low energy system. Riparian vegetation includes grasses, moss, fern, alder, and willow.

The proposed SHER 1 crossing is located 30 feet east of Goat Camp Road along the Copper River Highway. Downstream of the proposed SHER 1 crossing the stream will flow southwest and empties into a pond (old gravel pit) approximately 1000 feet downstream of the crossing.

The downstream channels predominant bedform features consist of riffles and pools with ponded marsh areas. The downstream channel is low gradient and banks are present at varying locations, vegetated with ferns and alders.

A reference reach was defined approximately 300 feet upstream of the Goat Camp Road crossing. Observed bankfull width ranged from 10.5 to 11.5 feet, with the bankfull depth ranging from 6 to 13 inches. The average channel slope is approximately 0.5 percent. Riffles and pools provide grade controls along the longitudinal profile and predominantly consist of gravel/ cobbles and woody debris. Sediment transport is low upstream and downstream of the crossing. A second reach was also reviewed directly downstream of the proposed SHER 1 crossing. Bankfull widths downstream of the proposed crossing ranged from 7.5 to 9.7 feet.

The observed stream characteristics of Sheridan River Tributary at SHER 1 are summarized in Table 1.

Stream Parameter	Existing Conditions
Slope	0.5 percent
Measured Bankfull Width	7.5 to 11.5 feet
Measured Bankfull Depth	6 to 13+/- inches
Bedform Features	Riffle-Pools

Table 1: Stream Characteristics of Sheridan River Tributary at SHER 1

The Goat Camp Road roadway embankment at SHER 02 is partially vegetated and eroding at the inlets and outlets. No end sections or headwalls are present at the SHER 1 culvert and the culvert is fully submerged, crushed, and corroded. There is approximately 5 feet of roadway cover over the existing culvert.

3.1.2 <u>COP 9</u>

The Sheridan River Tributary flowing to the COP 9 crossing originates in the marsh-wetlands southeast of the Sheridan River and crosses Goat Camp Road at the SHER 1 crossing. The Sheridan River Tributary follows the Copper River Highway and flows into COP 9. Additional water flows into the Sheridan River Tributary approximately 260 feet upstream of the COP 9 crossing and approximately 290 feet downstream of the SHER 1 crossing. The additional flow comes from a large, ponded marsh-wetland northeast of the crossing.

Upstream of the COP 9 Copper River Highway crossing, Sheridan River Tributary flows through a marsh area and the predominant bedform features consist of riffles and pools. Bank instability is indicated by several vegetated bars within the channel. The stream substrate consists of very fine to very coarse gravel with sections of sand and organics. It is a stable, low energy system. Riparian vegetation includes grasses, moss, fern, alder, and willow.

Downstream of the COP 9 Copper River Highway crossing, Sheridan River Tributary flows southwest and empties into a pond (old gravel pit) approximately 600 feet downstream of the crossing. The predominant bedform features consist of riffles and pools with ponded marsh areas. Downstream is low gradient and banks are present at varying locations, vegetated with ferns and alders. The stream substrate consists of very fine to very coarse gravel with sections of organics. Riparian vegetation includes grasses, moss, fern, alder, and willow. The floodplain is wide.

A reference reach was defined approximately 300 feet downstream of the Copper River Highway crossing. Observed bankfull widths ranged from 9.5 to 17 feet, with the bankfull depth ranging from 10 to 15 inches. The average channel slope is approximately 0.5 percent. Riffles and pools provide grade control along the longitudinal profile and predominantly rock formed, consisting of gravel and woody debris. Sediment transport is low upstream and downstream of the crossing.

The observed stream characteristics of Sheridan River Tributary at COP 9 are summarized in Table 2.

Stream Parameter	Existing Conditions
Slope	0.5 percent
Measured Bankfull Width	9.5 to 17 feet
Measured Bankfull Depth	10 to 15+/- inches
Bedform Features	Riffle-Pools

 Table 2: Stream Characteristics of Sheridan River Tributary at COP 9

The Copper River Highway roadway embankment at COP 9 is well vegetated. No end sections or headwalls are present at the Sheridan River Tributary COP 9 culvert. There is approximately 4 feet of roadway cover over the existing culvert.

3.2 Substrate Analysis

Pebble counts were completed on July 21 and 22, 2021. The D_{84} particle represents that size of which 84 percent of the streambed particles are expected to be smaller in size and is typically used as the basis for sizing rock that is only transported downstream during large flood events. Visual observations in the vicinity of the crossings agree with the pebble count results.

3.2.1 <u>SHER 1</u>

Three pebble counts were conducted at SHER 1. Pebble count 1 was performed 400 feet upstream of the crossing, pebble count 2 was performed 350 feet upstream of the crossing, and pebble count 3 was performed 35 feet downstream of the crossing. The average D_{84} particle size at SHER 1 was 46.7 mm. The armor layer at the SHER 1 crossing was found to range from very fine gravel to small cobble, with most of the stream substrate consisting of medium to very

coarse gravel. A summary of the pebble counts is shown in Figure 2 and Table 3.

For stream substrate design, a stream bed mix will be specified based on the particle size distribution of the natural substrate observed onsite and to mitigate entrainment of bed material during Q_{100} flows. This will allow for natural sediment transport through the proposed culvert. The Fuller-Thompson equations will be used to size particles smaller than the D₅₀ to provide adequate fines to fill voids and seal the simulation stream bed. Substrate design is included in Appendix B.

Particle	Count 1	Count 2	Count 3 35 feet Downstream	
Size	400 feet Upstream	350 feet Upstream		
D ₁₀₀ (mm)	90	128	90	
D ₈₄ (mm)	46.3	47.6	46.2	
D ₅₀ (mm)	23.7	24.3	21.1	

 Table 3: SHER 1 Pebble Count Summary

3.2.2 <u>COP 9</u>

Three pebble counts were conducted at COP 9. The pebble counts were performed at the three surveyed cross section locations. Pebble count 1 was performed 100 feet upstream of the crossing, pebble count 2 was performed 420 feet downstream of the crossing, and pebble count 3 was performed 365 feet downstream of the crossing. The average D₈₄ particle size at COP 33 was 49.5 mm. The armor layer at the COP 33 crossing was found to range from very fine gravel

to small cobble, with most of the stream substrate consisting of medium to very coarse gravel. A summary of the pebble counts is shown in Figure 3 and Table 4.

For stream substrate design, a stream bed mix will be specified based on the particle size distribution of the natural substrate observed onsite and to mitigate entrainment of bed material during Q_{100} flows. This will allow for natural sediment transport through the proposed culvert. The Fuller-Thompson equations will be used to size particles smaller than the D₅₀ to provide adequate fines to fill voids and seal the simulation stream bed. Substrate design is included in Appendix B.

Particle	Count 1	Count 2	Count 3	
Size	100 feet 420 feet Upstream Downstream		365 feet Downstream	
D ₁₀₀ (mm)	90	90	90	
D ₈₄ (mm)	50.3	52.2	45.2	
D ₅₀ (mm)	27.8	30.8	28.8	

Table 4: COP 9 Pebble Count Summary

4.0 HYDROLOGIC ANALYSIS

4.1 Drainage Area Characteristics

The Sheridan River Tributary COP 9 and SHER 1 drainage basin flowing to Goat Camp Road and the Copper River Highway is approximately 438 acres (0.69 square miles) in size. The drainage basin is undeveloped and consists of wetlands, ponds (old gravel pits), and forested area within the glacial outwash area.

4.2 Methodology

Two methods of quantifying flow were compared to identify the most appropriate design discharge likely experienced by the crossings. Cordova's interconnected floodplain hydrology is difficult to accurately capture using the USGS regional regression equations. For these crossings, the flow estimates derived from the regression equations were supplemented by flow estimates derived from stage-discharge measurements at COP 9 completed by the USFWS.

The 2003 and the 2016 Regional Regression Equations were used to estimate peak discharges for the Sheridan River Tributary crossings. The 2016 Regional Regression Equations, published by the United States Geological Survey (USGS) in the Scientific Investigations Report 2016-5024, were used to estimate peak discharges for both crossings. The USGS PRISM data for the drainage areas was used to find a mean annual precipitation value of 106.28 inches for COP 9 and SHER 1. The drainage basin for COP 9 and SHER 1 is within the 0.4 square mile lower limit area and 1,000 square mile upper limit area and the annual precipitation is within the range of 8 to 280 inches on which the regression equations were developed. Therefore, the regression equations are expected to return reasonable flow estimates. Results of the 2016 Regional Regression Equations were compared to the results of the 2003 USGS Regional Regression Equations published by the USGS in Water-Resources Investigations Report 03-4188. For the 2003 USGS Regional Regression Equations, drainage basin areas, surface storage, and mean annual precipitation data were input into empirically derived equations to predict peak flow for varying recurrence intervals. A mean annual precipitation of 180 inches and a mean minimum January temperature of 16 degrees Fahrenheit was used for this analysis, as estimated from Plate 1 and 2 of the USGS publication Water-Resources Investigations Report 93-4179 Magnitude and Frequency of Floods in Alaska and Conterminous Basins of Canada (Jones & Fahl, 1994) in accordance with procedures listed in WRI 03-4188. The drainage area, temperature and storage percentage for both basins are within the acceptable range of variables for input. The 2003 USGS mean annual precipitation of 180 inches based on plate 2 is higher than 106.28 inches from the USGS PRISM data. Mean annual precipitation averages from three NOAA gages in Cordova range from 86.18 inches to 168.64 inches. The USGS Regional Regression Equation computations are included in Appendix C.

The stage was measured at COP 9 for two years. Flow measurements taken in the field by CRWP and USFS to generate stage-discharge relationships for the gauges and were correlated to the USGS Glacier Tributary gauge. A log-Pearson Type III analysis was conducted to estimate the flood frequency of the respective systems.

4.3 Results of Flood Flow Analysis

4.3.1 SHER 1 and COP 9

The peak runoff flows for each analysis method for SHER 1 and COP 9 are shown in Table 5.

Storm Event (year)	2016 Regional Regression (cfs)	2003 Regional Regression (cfs)	LPIII Flood Frequency Estimate (cfs)
2	81.4	110.0	18.3
5	131.0	145.0	24.0
10	169.0	170.0	27.4
25	221.0	201.0.	31.5
50	261.0	224.0	34.4
100	305.0	246.0	37.1

Table 5: Estimated Peak Flows for SHER 1 and COP 9

Notes: cfs = cubic feet per second

The flow estimates derived from measured stage at the site is significantly lower than the USGS regression equation estimates. The flow estimates based on measured stage appear to match observations made during the July 2021 site visits. Given the observations at site and size of the contributing basin, it appears that log-Pearson Type III estimates are appropriate to size the rehabilitated channel section.

Per the criteria identified in the project objectives, culverts for SHER 1 and COP 9 have been evaluated for hydraulic capacity based on the 100-year peak flow of 37.1 cubic feet per second (cfs). The Copper River Delta is a dynamic system and flow routing upstream across Goat Camp Road can shift over time supplying disproportionate flow to either COP 9 and/ or SHER 1. As such COP 9 and SHER 1 were evaluated under two scenarios. Scenario 1; Watershed is evenly split to each culvert. (50% Q100=18.3). Scenario 2; Entire watershed is directed to a single culvert (Q100=37.1). Results of the HY-8 analyses for the proposed culvert options are included in Section 7.0 Recommendations.

5.0 HYDRAULIC ANALYSIS

5.1 Bankfull Velocity and Discharge Estimates

The bankfull discharge and velocity were calculated for the measured cross section based on the cross section hydraulic dimensions, bankfull slope, and Manning's Equation using the River Stability Field Guide worksheets to check that average bankfull velocity is between 2.5 to 5 feet per second (fps) and that the bankfull discharge is close to the 2-year flood flow. Calculated bankfull velocity and discharge from the worksheet is shown below and based on guidance from the USFWS *Fish Passage Design Guidelines (Revision 6).* River Stability Field Guide worksheets are included in Appendix D.

Bankfull VELOCITY & DISCHARGE Estimates								
Stream:	Stream: Sheridan River Tributary Location:				Cordova	, AK

1. Friction Factor	1. Friction Relative $\bar{u} = [2.83 + 5.66 * Log \{ R/D_{84} \}] u$ Factor Roughness			/D ₈₄ }]u*	2.47	ft / sec	22.84	cfs
2. Roughness Roughness (F	2. Roughness Coefficient: a) Manning's <i>n</i> from Friction Factor/Relativ Roughness (Figs. 2-29, 2-30) $\bar{u} = 1.49 * R^{2/3} * S^{1/2} / n$ $n = 0.045$				2.03	ft / sec	18.78	cfs

Figure 4: SHER 1 Bankfull velocity and discharge estimates

At SHER 1 an 8.42-foot bankfull riffle width, 1.1-foot depth resulted in the calculated 18.78 cfs and 22.84 cfs bankfull discharge for the crossings which is between the 2 and 5-year storm event for the estimated peak flows (Figure 4). At COP 9 an 8.42-foot bankfull riffle width, 1.3-foot depth resulted in the calculated 24.20 cfs and 30.14 bankfull discharge for the crossings which is between the 5 and 25-year storm event for the estimated peak flows.

5.2 HY-8 Analysis

The Federal Highway Administration's HY-8 software was used for the hydraulic analysis of proposed culverts. The software was used to model the hydraulic capacity at the 2-year, 50-year and 100-year flow and calculate the overtopping flow. Results of the HY-8 analyses for the proposed culvert options are included in Section 7.0 Recommendations. Structures were selected for analysis based on span dictated by the measured bankfull widths, watershed split flows and HW/D ratios.

5.3 Low Flow Channel

5.3.1 <u>COP 9 and SHER 1</u>

The low-flow channels for the COP 9 and SHER 1 crossings were calculated based on guidance from the USFWS *Fish Passage Design Guidelines (Revision 6)*. A "V" shaped thalweg with a cross-sectional area of 15 to 30 percent of the bankfull cross-sectional area and a minimum depth of four inches for small streams and up to twelve inches for larger streams was used for design of the low-flow channels.

6.0 DESIGN ALTERNATIVES

Design guidelines recommend that culvert span for proposed replacement structures should be at least 1.0 times bankfull width. One of the main design parameters in the analysis of design options is the HW/D: a numerical representation of the depth of the water (headwater depth) at the culvert inlet to the height (depth) of the culvert relative to the stream bed. For stream simulation design, a HW/D of 0.8 or less is desirable when economically reasonable to reduce the likelihood for scour of bed material within the culvert during flood events and to provide freeboard for passing debris during flood events. A combination of measured bankfull information and HW/D ratios was used to determine acceptable structures for the crossings.

Several replacement alternatives have been evaluated including various aluminum pipe arch culvert sizes at COP 9 and SHER 1. Applicable culvert shapes for each crossing were determined with consideration given to groundwater elevations and available cover over the pipe.

Aluminum and steel structural pipe arch and round culvert options were considered, as well as aluminum and aluminized steel corrugated pipe arch and round culverts.

Culvert replacement options considered for COP 9 and SHER 1 include:

- 6-foot, round aluminum culvert embedded 2.0 feet. Approx. (Q100 HW/D=0.72)
- An 8-foot, 5-inch span by 6-foot, 3-inch rise aluminum box culvert embedded 2.0 feet Approx. (Q100 HW/D=0.68),
- A 9-foot, round aluminum culvert embedded 3.0 feet. Approx. (Q100 HW/D=0.58)
- A 10-foot, 11-inch span by 6-foot, 4-inch rise aluminum box culvert embedded 2.6 feet Approx. (Q100 HW/D=0.43),
- A 12-foot, 1-inch span by 6-foot, 7-inch rise aluminum box culvert embedded 2.6 feet Approx. (Q100 HW/D=0.37),
- A 13-foot, 3-inch span by 6-foot, 9-inch rise aluminum box culvert embedded 2.8 feet Approx. (Q100 HW/D=0.32), and
- A 15-foot, 4-inch span by 6-foot, 5-inch rise aluminum box culvert embedded 2.6 feet Approx. (Q100 HW/D=0.31).

7.0 RECOMMENDATIONS

7.1.1 <u>SHER 1</u>

Replacing the crushed culverts at the Goat Camp Road crossing with an 8-foot, 5-inch span by 6-foot, 3-inch rise aluminum pipe arch culvert is recommended to improve fish passage, increase watershed connectivity and flood conveyance. It is recommended that the culvert be relocated to span the Copper River Highway 30 feet to the east of Goat Camp Road.

This replacement option is anticipated to convey the Q_{100} of 37.1 cfs and the Q_{50} of 34.4 cfs from Scenario 2 with a HW/D ratio of approximately 0.68 and 0.58, respectively. The pipe arch culvert will be embedded 2.0 feet. Minimum allowable cover over the culvert is 2 feet and maximum allowable cover over the culvert is 16 feet. Roadway overtopping would occur at a flow of approximately 190 cfs.

Scenario	Storm Event	LPIII Flood Frequency Estimate (cfs)	Depth	HW/D
Scenario 1	2-Year	9.2	1.3	0.52
Scenario 1	50-Year	17.2	1.6	0.57
Scenario 1	100-year	18.6	1.7	0.58
Scenario 2	2-Year	18.3	1.7	0.58
Scenario 2	50-Year	34.4	2.2	0.67
Scenario 2	100-year	37.1	2.3	0.68

Table 6: Estimated HW/D for SHER 1

Notes: Scenario 1: Watershed is evenly split to each culvert.

Scenario 2: Watershed is directed to single culvert.

The recommended culvert meets the criteria to accommodate the theoretical 100-year flood flow with a HW/D ratio of less than 0.8. The capacity calculations for the culvert assume that all runoff upstream of the culvert is conveyed however, due to the ephemeral nature of the upstream floodplain, it is anticipated that the upstream banks will overtop and utilize floodplain storage before the HW/D reaches 0.68. No overtopping of the existing culvert has been noted during storm events, inferring that upstream storage and flow rerouting or storage of runoff upstream of COP 9 occurs. No reconstructed stream banks on each side of the channel will be placed in this pipe due to the shallow grade of the system. The culvert will be embedded with waterway bed material to mimic natural substrate. The simulated stream channel inside will be constructed as a roughened riffle. Reconstructed stream banks upstream and downstream from the culvert will consist of vegetated mats. The embankment slopes will be stabilized with Class I riprap to provide erosion protection.

An aluminum pipe was selected due to the higher corrosion resistance and longevity, ease of construction, low cost, and availability.

Culvert Width	8-foot, 5-inch
Bankfull Width	7.5 feet
Ratio	1.1

Table 7: Ratio of Culvert Width to Bankfull Width

7.1.2 <u>COP 9</u>

Replacing the 4-foot diameter round culvert at the COP 9 Copper River Highway crossing with an 8-foot, 5-inch span by 6-foot, 3-inch rise aluminum pipe arch culvert is the recommended option for improving fish passage and flood conveyance at the Copper River Highway crossing.

This replacement option is anticipated to convey the Q_{100} of 37.1 cfs and the Q_{50} of 34.4 cfs from Scenario 2 with a HW/D ratio of approximately 0.68 and 0.58, respectively. The pipe arch culvert will be embedded 2.0 feet. Minimum allowable cover over the culvert is approximately 2 feet and maximum allowable cover over the culvert is approximately 16 feet. Roadway overtopping would occur at a flow of approximately 210 cfs.

Scenario	Storm Event	LPIII Flood Storm Frequency Event Estimate (cfs)		HW/D		
Scenario 1	2-Year	9.2	1.3	0.52		
Scenario 1	Scenario 1 50-Year		1.6	0.58		
Scenario 1	100-year	18.6	1.7	0.59		
Scenario 2	2-Year	18.3	1.7	0.59		
Scenario 2	50-Year	34.4	2.2	0.67		
Scenario 2	100-year	37.1	2.3	0.69		

Table 8: Estimated HW/D for COP 9

Notes: Scenario 1: Watershed is evenly split to each culvert.

Scenario 2: Watershed is directed to single culvert.

The recommended culvert meets the criteria to accommodate the theoretical 100-year flood flow with a HW/D ratio of less than 0.8. The capacity calculations for the culvert assume that all runoff upstream of the culvert is conveyed however, due to the ephemeral nature of the upstream floodplain, it is anticipated that the upstream banks will overtop and utilize floodplain storage before the HW/D reaches 0.68. No overtopping of the existing culvert has been noted during storm events, inferring that upstream storage and flow rerouting or storage of runoff

upstream of COP 9 occurs. No reconstructed stream banks on each side of the channel will be placed in this pipe due to the shallow grade of the system. The culvert will be embedded with waterway bed material to mimic natural substrate. The simulated stream channel inside will be constructed as a roughened riffle. Reconstructed stream banks upstream and downstream from the culvert will consist of vegetated mats. The embankment slopes will be stabilized with Class I riprap to provide erosion protection.

An aluminum pipe was selected due to the higher corrosion resistance and longevity, ease of construction, low cost, and availability.

Adjusting the SHER 1 culvert to provide more watershed connectivity across the Copper River Highway will improve the conveyance of the system and provide a more natural flow path. By redirecting flow from SHER 1 across the Copper River Highway, COP 9 will receive less flow than current conditions. COP 9 is designed assuming that the current hydrologic conditions will change. Bankfull indicators were not present in the wetland complexes upstream of the COP 9 culvert, therefore bankfull widths were taken downstream of the culvert, which include the SHER 1 flow. The culvert width to bankfull width ratio is less than the recommended minimum of 1.0 (Table 9). The reference reach bankfull width may not be representative of future conditions after construction (to exclude the SHER 1 flow). This criterion was reviewed but not used for the COP 9 design.

Table 9: Ratio of Culvert Width to Bankfull Width

Culvert Width	8-foot, 5-inch
Bankfull Width	9.5 feet
Ratio	0.9

7.2 Rejected Alternatives

7.2.1 <u>SHER 1 and COP 9</u>

An aluminum structure is recommended over steel due to the lower weight of material, higher corrosion resistance and the potential for faster installation reducing the traffic restrictions on the Copper River Highway. All steel structures were eliminated from the designs.

SHER 1 and COP 9 both considered the 10-foot, 11-inch span by 6-foot, 4-inch rise aluminum box culvert embedded 2.6 feet, the 13-foot, 1-inch span by 6-foot, 9-inch rise aluminum box culvert embedded 2.6 feet, and the 15-foot, 0-inch span by 6-foot, 7-inch rise aluminum pipe arch embedded 2.6 feet but were eliminated due to HW/D ratio.

Round structures were considered at COP 9 but due to the available cover over the pipe and water surface elevations at the project location, the structures were eliminated. The 6-foot round aluminum culvert embedded 2.0 feet was eliminated due to a bankfull width ratio of 0.63. The 9-foot round aluminum culvert embedded 3.0 feet was eliminated due to minimum cover requirements.
